

Replicator Application Note

Medical Imaging

The Problem

The medical imaging field presents some unique problems in that, although images are produced at one location, medical professionals may need to view them at one or more different locations. Is there a simple solution that can centralize the images and provide them to the various viewing stations?

The Solution

A Replicator server established at a central location can pull the images from the production points, over the Internet, with all the viewing stations pointing to the central location. If faster access becomes an issue at a remote location, a separate Replicator server can be set up at that site to pull images from the central server on a regular basis, which would provide a local copy with fast viewing access.
